Arm Yourself for Dry AMD

It's imperative we prepare ourselves with up-to-date information for better care of our patients. **By Andrew J. Rixon, OD, Richard C. Trevino, OD, and Roya Attar, OD**

Age-related macular degeneration (AMD) is the leading cause of vision loss in individuals 65 and older.[1] By the year 2020, it will affect an estimated 196 million people worldwide.[1] Vision loss from AMD can be functionally and emotionally debilitating, as it can make it difficult, or even impossible, to read, drive, enjoy certain hobbies and maintain an independent lifestyle.[2]

Approximately 90% of those with AMD have the dry form, for which there is currently no treatment—only lifestyle modifications to reduce risk of progression. Roughly 10% of those with AMD develop choroidal neovascular membranes (CNV), yet it accounts for 75% of severe vision loss in those with AMD.[3]

The capacity for proper detection, education and management of AMD is essential for optometrists, and staying current on the ever-changing body of information surrounding the disease allows for best patient outcomes. This article reviews the pathophysiology of dry AMD, risk factors, diagnostics and patient follow up to ensure clinicians are ready when patients present with suspicious findings. While there is no treatment as of yet, review of current clinical trials suggests one might await us in the future.

Pathophysiology

Retinal health is contingent on the relationship between photoreceptors and the retinal pigment epithelium (RPE).[4] The RPE functions as a protector against photo-oxidative damage to the retina and transports nutrients between the choriocapillaris and retina.[4] To avoid photo-oxidative damage, photoreceptors undergo a daily renewal process where roughly 10% of their volume is shed, then phagocytosed by the RPE.[4]

Foundationally, the accumulation of photo-oxidized debris within and under the RPE is considered the initiating cause of AMD.[5] The debris found within the RPE cells includes a yellow-brownish pigment granule called lipofuscin—a lipid-containing residue from lysosomal digestion with autofluorescent properties.[6]

Release Date: January 2017
Expiration Date: January 15, 2020
Goal Statement: Proper AMD detection, education and management is essential, and staying current on information surrounding the disease allows for best patient outcomes. This article reviews the pathophysiology, risk factors, diagnostics and patient follow up to ensure clinicians are ready for these patients.

Fig. 1. Fundus photography with corresponding OCT images of small, intermediate and large drusen.

Drusen, composed of acellular, polymorphous material, is considered the hallmark of early AMD.[7] Hard drusen involve focal thickening of the RPE basement membrane and may become calcified, lipidized, cholesterolized or, rarely, vacscularized.[8] Soft drusen are substantially larger than hard drusen and represent a limited separation of the RPE basement membrane from its attachment to Bruch's membrane.[8]

Drusen size and RPE abnormalities are important risk factors for progression of AMD (*Figure 1*).[9] RPE cells, in response to many negative stimuli, go through morphological changes such as hypertrophy, atrophy and intraretinal migration.[7]

Small drusen (<63µm) are consistent with the normal aging process and have no relevant increased risk of late AMD developing.[10] In fact, small drusen (<31.5µm) are common in persons younger than 50, with reported incidence as high as 95.5%.[3,11,12]

Medium drusen (63µm to 125µm) have not been studied extensively, but a recent study found that patients with large total macular areas involving medium drusen, and closer proximity of these to the fovea, were more likely to progress to early AMD.[13] Medium drusen confers an increased risk of progression to late AMD, although this risk is not great.[10,13] However, the presence of both medium drusen and RPE abnormalities (within two disc diameters of the fovea) increases the risk of progression to late AMD by between four and ten-fold compared with the presence of medium drusen alone.[10,13]

Large drusen (>125µm) are associated with a much higher risk for developing advanced AMD, with an estimated five-year rate of developing late AMD of 13% when found bilaterally without other abnormalities.[10,9] That five-year risk of progression increases to 47.3% when there is the bilateral presence of both large soft drusen and pigmentary abnormalities (*Figure 2*).[10]

The width of a major branch retinal vein as it crosses the optic disc margin is approximately 125µm and is a good reference to estimate the size of retinal drusen.[10]

The natural history of drusen is dynamic, and multiple studies confirm that both resorption of drusen and the formation of new drusen can occur simultaneously in the same macula.[9,14] Recent preliminary SD-OCT studies show a tendency for drusen to increase in volume and area over time, although regression can also occur (*Figures 3a and 3b*).[9,15] In the observation group of one study, the proportion of eyes showing a reduction of ≥50% in the area of drusen within 3,000µm of the foveal center increased over time from 1.2% at six months to 31.2% at five years.[16]

Although regression of drusen volume may seem to be a positive outcome, this usually progresses to outer retinal atrophy and loss of underlying choroidal thickness.[17] Investigators found that larger drusen volume is more likely to spontaneously regress, followed by possible progression to geographic atrophy (GA) or CNV.[9] Additional studies show that increased drusen volume with spontaneous regression is a negative prognostic indicator for advancement of the disease.[18,19]

Reticular pseudodrusen (RPD) has recently been recognized as another expression of AMD. RPD are associated with changes internal to the RPE and are predominantly located outside the fovea. RPD is highly correlated with GA, a known risk factor for advanced AMD.[20] Approximately 30% to 50% of patients with RPD progress to late AMD.[21] In the Beaver Dam eye study, patients with RPD had a six-fold higher rate of progression to late AMD than patients with indistinct soft drusen alone.[22]

Geographic atrophy occurs when the RPE, overlying photoreceptors and underlying choriocapillaris break down in a sharply demarcated area, revealing underlying choroidal vessels.[22-25] Research estimates it accounts for 35% to 40% of late-stage AMD cases.[26] GA develops frequently in macular areas previously occupied by drusen.[24] Once GA develops, the atrophic area typically enlarges slowly and in a non-central location, ultimately involving the

central macula and resulting in vision loss.[23,27,28]

AMD Risk Factors

Some risk factors for AMD are modifiable, while others are not:

Non-modifiable Risk Factors

Age. The most important risk factor for AMD is age itself. The prevalence of AMD among 60-year-olds is 0.9%.[26,29] At age 70 it rises to 2.8%, and among those older than 80 the prevalence jumps to over 10%.[26,29] Although the reason for this strong association is not clearly understood, both local retinal and broader systemic age-related changes are believed to play a role.

Ethnicity. Research suggests the prevalence of AMD varies widely among racial and ethnic groups. In North America, studies estimate AMD is twice as prevalent among Caucasians compared with African Americans, while late-stage AMD is roughly 10 times more prevalent among Caucasians than African Americans.[29,30]

Genetic factors. Close relatives of people with AMD are at an increased risk for the condition.[31] Studies of twins reveal that the heritability of AMD ranges between 46% and 71%, with severe AMD being more heritable than the mild form of the disease.[32]

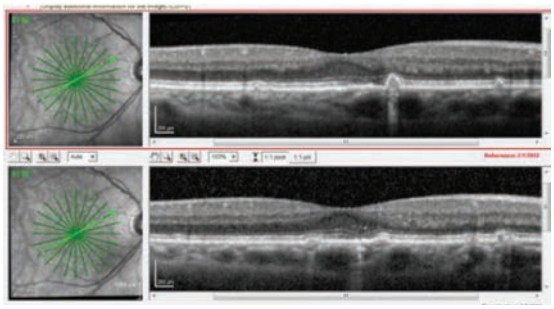

Fig. 3a. Radial OCT slice showing spontaneous regression of large drusen.

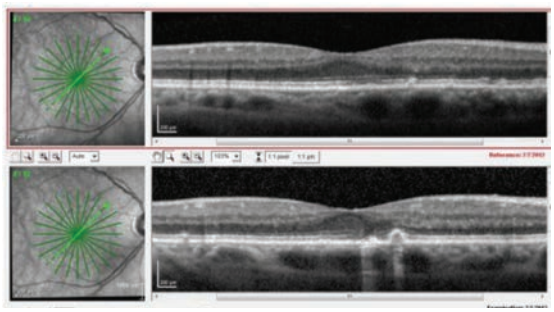

Fig. 3b. Radial slice in same patient, in same time frame, showing increased size and formation of large drusen.

Currently, 52 genes have been identified involved with AMD risk. Two genes in particular seem to convey the greatest risk.[33] One is for a protein in the complement inflammatory pathway known as complement factor H (CFH). The second gene remains elusive, but studies have narrowed it down to either age-related maculopathy susceptibility gene number 2 (ARMS2) or a gene that codes for the protein high temperature requirement factor A1 (HTRA1), which plays a role in angiogenesis.[34]

Both CFH and ARMS2 were associated with higher rates of disease progression in the mostly white participants of the AREDS study, but the effect of these genes may vary with race.[35] For example, it appears ARMS2 has little or no effect on AMD risk in African Americans.[36] The risk associated with these two genes is additive, so a person with both high-risk genes is at greatest risk.[37] Individuals possessing high-risk genes are not only more susceptible to developing AMD, but are also at elevated risk of having the disease progress to legal blindness.

Low macular pigment. This is another important AMD risk factor.[38] Macular pigment is composed of the carotenoids lutein, zeaxanthin and meso-zeaxanthin, which have both blue light filtering and antioxidant properties. Low macular pigment is associated with low dietary intake of foods rich in these compounds such as spinach, kale and eggs. Other factors contributing to low macular pigment include genetics, obesity and smoking.[39]

High macular pigment optical density (MPOD), found using heterochromatic flicker photometry, is believed to protect the retina against photo-oxidative damage caused by blue light.[38] Individuals with low MPOD are at elevated risk of AMD, and may also suffer from decreased visual function owing to the blue light filtering effect of macular pigment.[38]

Modifiable Risk Factors

Tobacco. By far the most important modifiable risk factor for AMD is smoking tobacco products, and it remains the only established causative factor for AMD.[40]

Compared with someone who has never smoked, current smokers have two to three times greater risk of developing the disease.[41] In addition, smokers develop AMD at a younger age than nonsmokers and have a higher risk of disease progression.[42]

Smoking cessation results in a risk reduction that increases with duration of abstinence from tobacco. Several long-term, population-based studies found that former smokers are at only slightly higher risk than individuals who have never smoked.[40]

Lifestyle. In addition to smoking cessation, a number of other lifestyle changes can decrease AMD risk, including maintaining an average body weight, getting regular exercise and eating a heart-healthy diet.[43] In fact, a combination of healthy lifestyle practices might be more important in reducing AMD risk than a focus on any given one. A healthy lifestyle can reduce oxidative stress and inflammation throughout the body, both of which are thought to promote AMD.

Increased exposure to sunlight. This has been identified as a potential AMD risk factor, and it appears to be greatest in those with light hair and eye color.[44,45] Known as the *blue light hazard*, short wavelength, high energy, visible blue light triggers the release of harmful free radicals in the retina that cause oxidative stress, possibly contributing to the development of AMD.[46] Measures that protect the eyes from sunlight, including broad-brimmed hats and blue light filtering sunglasses, can mitigate this risk.[47] The yellowing of the crystalline lens with age will naturally decrease the amount of blue light that reaches the retina as a patient ages. However, cataract surgery can eliminate this protective effect, thereby increasing AMD risk.[41] Many intraocular lens implants now contain blue light filtering properties. The AREDS study found no association between cataract surgery and subsequent progression of AMD.[48]

Associated Findings

Dark adaptation. In addition to a variety of visual changes, self-reported complaints of difficulty under dim lighting or at night are common in patients with AMD.[49] Consistent with this complaint, delayed rod-mediated dark adaptation is characteristic of early AMD, which can also be observed in some older adults with normal macular health, whereas cone-mediated dark adaptation in the same retinal area is undisturbed.[50]

In early AMD, photoreceptor degeneration is associated with decreased light sensitivity in the macula and slowed dark adaptation, despite relatively unimpaired visual acuity.[51] Research suggests this is likely due to changes within the RPE/Bruch's membrane complex, where drusen are formed.[49,51] Drusen accumulate in the aging Bruch's membrane and in the sub-RPE space in

early AMD, disrupting the retinoid cycle and leading to photoreceptor degeneration, with an earlier onset and more severity affecting macular region rods than the cones.[50,52] Other potential factors contributing to the scotopic dysfunction in early AMD include genetic alterations in vitamin A metabolism and age- and disease-related deficits in pathways within the RPE metabolism that remain uncharacterized. Regardless of the exact mechanisms underlying the slowed rod-mediated dark adaptation, a scotopic functional impairment is present in the earliest phases of AMD.[50]

One study concluded that delayed rod-mediated dark adaptation in older adults with normal macular health is associated with incident-early AMD three years later, and thus is a functional biomarker for detection of early disease.[53]

Research has also found increasing age, decreasing visual acuity, the presence of reticular pseudodrusen, severity of AMD and decreased subfoveal choroidal thickness are also associated with dark adaptation impairments.[54]

Imaging in Dry AMD

Standard color fundus photography, although historically useful for classifying the stage of AMD, may not adequately detect some common early and intermediate manifestations.[55,56] RPE damage is a hallmark of AMD, and alterations to the RPE may not be clinically detectable by funduscopy or photography. Drusen and subretinal drusenoid deposits become clinically visible at 30µm while changes in RPE cells are substantially smaller.[57] *In vivo* imaging of the autofluorescent properties of the ocular fundus provides the ability to visualize and evaluate the state of the aging RPE in AMD.[58]

Studies show innate autofluorescent properties originate from the accumulation of fluorescent pigments, known as fluorophores, in the RPE cells, primarily as lipofuscin.[58] Fundus autofluorescence (FAF) noninvasively visualizes these fluorophores with a short wavelength excitation light, followed by capture of the fluorescence signals emitted post excitation.[59] Areas of abnormal autofluorescence are then compared with a normal, homogenous autofluorescent background and are described as having increased or decreased autofluorescence.[60] GA, for instance, exhibits dark areas because of a complete lack of fluorophores.[60] FAF thus provides a topographical rendering of the extent of lipofuscin accumulation in the RPE.[8]

Using these renderings, researchers have described and classified distinct patterns of abnormal fundus autofluorescence in early nonexudative AMD—and, most importantly, suggest they are useful in determining the risk of disease progression.[58,59,61] Furthermore, researchers have used FAF to demonstrate not only progression in patients with GA, but also inhibition of progression when therapeutic intervention is successful (*Figure 4*).[59,62,63] A recent study shows that FAF imaging detects GA earlier than with color photography, in part due to precise delineation of GA borders as a result of superior contrast (*Figures 5a and 5b*).[28] However, FAF's advantage over color photography diminishes over time, with the two modalities ultimately becoming comparable in more advanced cases.[64]

FAF is also highly beneficial in imaging RPD. The appearance of these drusen vary based on imaging techniques, and their extent of involvement can be difficult to detect with fundus evaluation alone.[20]

Follow-up Evaluation

A history and examination are the recommended elements of follow-up visits. The follow-up history should take into account symptoms, including decreased vision and metamorphopsia, as well as changes in medications, nutritional supplements, medical, ocular and social history. The examination on the follow-up visit should include visual acuity and stereoscopic biomicroscopic examination of the fundus.[80,81]

Recommended follow-up intervals, assessment and treatment plans for non-neovascular AMD are listed below.[80,8]

Treatment Recommendations and Follow Up for Non-neovascular AMD

Type of Patient	Frequency of Examination	Follow-up Recommendations	
		Management Plan	Testing
Patients with two or more risk factors for AMD, older than age 55	Annual examination if asymptomatic, or prompt examination if new symptoms	• Patient education • Recommend UVR protection, antioxidant supplementation, home Amsler or comparable monocular near vision self-monitoring weekly	• Baseline fundus photos, repeat every two years or as necessary • Stereo fundus biomicroscopy • Amsler grid • Baseline central 10 degrees • Automated visual field, repeat every two years • OCT and/or fluorescein angiography as appropriate
Patients with hard drusen, pigmentary degeneration or both	Six to 12 months, depending on risk factors	• Patient education • Recommend UVR protection, antioxidant supplementation, home Amsler or comparable monocular near vision self-monitoring twice each week	• Fundus photos, repeat every two years or as necessary • Stereo fundus biomicroscopy • Amsler grid • Central 10 degrees • Automated visual field, repeat every two years • OCT and/or fluorescein angiography as appropriate
Patients with geographic atrophy, VA 20/30 to 20/70	Six to 12 months, depending on extent of atrophy	• Patient education • Recommend UVR protection, antioxidant supplementation, home Amsler or comparable monocular near vision self-monitoring every other day • Monitor for CNV	• Fundus photos every year • Stereo fundus biomicroscopy every interim visit • Amsler grid every interim visit • Central 10 degrees • Automated visual field every one to two years • OCT and/or fluorescein angiography as appropriate
Patients at high risk with soft confluent drusen and granular pigmentary degeneration	Four to six months	• Patient education • Recommend UVR protection, antioxidant supplementation, home Amsler or comparable monocular near vision self-monitoring daily • Low vision consultation and evaluation	• Annual fundus photos • Stereo fundus biomicroscopy every interim visit • Amsler grid every interim visit • Annual central 10 degrees • Automated visual field, • Consider central 30° AVF depending on central fixation • OCT and/or fluorescein angiography as appropriate
Patients with geographic atrophy in both eyes	Six to 12 months	• Patient education • Low vision consultation and evaluation	• Annual fundus photos • Stereo fundus biomicroscopy every interim visit • Annual central 10 degrees • Automated visual field

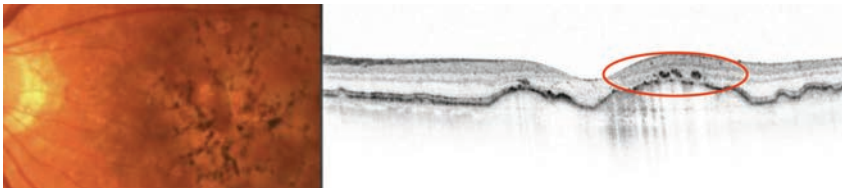
These lesions tend to show well on FAF and infrared reflectance imaging (*Figure 6*).[20]

OCT has become increasingly valuable in AMD assessment, as it provides noninvasive, high-resolution, cross-sectional imaging of both the neurosensory and deeper subretinal layers.[66] SD-OCT has proven useful for evaluating drusen of all sizes, drusenoid PEDs, changes to neurosensory retina overlying drusen, reticular pseudodrusen, retinal pigment abnormalities, GA and age-related choroidal atrophy.[7]

Specifically, small to medium drusen will exhibit variable reflectivity depending on the composition of the underlying material. Large drusen or drusenoid PEDs will often show a dome-shaped elevation of the RPE with a hypo- or medium-reflective material separating the RPE from the underlying Bruch's membrane.[7] Pigment clumping and migration will appear focally hyper-reflective with underlying shadowing (*Figure 7*). Focal loss of RPE will show hyporeflectivity in the RPE and hyper-reflectivity of the underlying choroidal vessels.[7] Lastly, GA appears as areas of sharply demarcated choroidal hyper-reflectivity. There may be associated retinal atrophy manifesting with thinning or loss of the outer nuclear layer and the absence of the external limiting membrane and inner segment-outer segment junctions (*Figure 8*).[7]

Current Clinical Trials

Currently, medical treatment options for AMD are limited to only patients whose disease leads to the development of CNV. With anti-vascular endothelial growth factor (VEGF) treatment for these particular patients, the visual prognosis for exudative AMD has improved drastically, but investigators are still evaluating multiple targets and different



Photos: Mohammad Rafieetary, OD

Fig. 7. Pigmentary migration imaged with OCT shows increased hyper-reflectivity (darker with reverse contrast scan) and causes shadowing of underlying RPE layer.

delivery systems to further improve treatment for those with CNV from AMD. Additionally, researchers are making significant progress in helping dry AMD patients who suffer vision loss from GA.

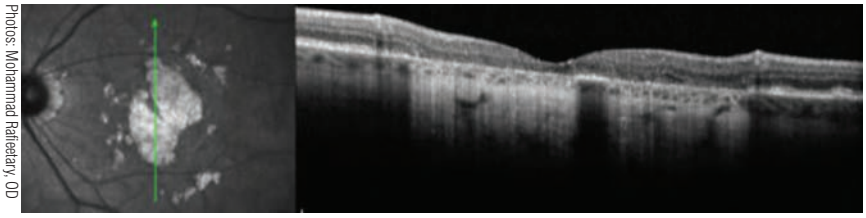
One goal for future AMD treatment is improving treatment efficacy by targeting multiple steps simultaneously in the pathogenesis of CNV development. Two drug targets researchers are currently considering are angiopoietin 2 and platelet-derived growth factor (PDGF), as both play key roles in the formation of new blood vessels.[66] Investigators are also evaluating the molecule RG7716 in phase II clinical trials of the AVENUE study.[67] It is an anti-VEGF molecule, but also exhibits anti-angiopoietin 2 properties.[68] Fovista (Ophthotech) is an anti-PDGF molecule that has completed phase II trials, and preliminary results show increased efficacy when used in conjunction with ranibizumab compared with ranibizumab alone.[69,70] It is currently in phase III clinical trials.[71,72]

Another emphasis in AMD therapy is relieving patient's burden of treatment. Although current anti-VEGF therapy provides extreme improvement in visual outcomes for those with wet AMD, many patients maintain visual stability only with periodic injections, often monthly, for an indefinite length of time. The ongoing LADDER study is evaluating the feasibility of a port delivery system to give sustained release of medication in those with wet AMD.[73] Additionally, the phase III clinical trial HAWK is evaluating the efficacy of an anti-VEGF agent, RTH258, that could decrease the time between retreatment in patients with CNV.[74]

RTH258 is currently the smallest VEGF inhibitor used in human therapy. Due to its small molecular size, it can be given in higher concentrations, hopefully leading to longer duration of action. In initial phase II studies, researchers show it is non-inferior to ranibizumab one-month post treatment and had longer effect of treatment than ranibizumab.[75]

The most promising treatment options on the horizon for GA are complement inhibitors, which aim to decrease the rate of progression of GA. Phase II clinical trials with intravitreal dosing show lampalizumab, a complement factor D inhibitor, is a safe treatment option for GA and has potential efficacy in reduction of GA progression at 18 months.[76] Currently there are two ongoing identical phase III trials, CHROMA and SPECTRI, to determine lampalizumab's efficacy.[77,78]

While lampalizumab is a promising treatment option, other complement inhibitors have failed to show efficacy. For example, eculizumab, a factor C5 inhibitor, failed to show efficacy in reduction of GA progression in phase III clinical trials.[79]



Photos: Mohammad Rafieetary, OD

Fig. 8. OCT image of GA shows increased light transmission to the choroid due to absence of RPE. The outer retinal layers are also lost in the regions of GA.

With rising incidence of AMD in the aging US population, optometrists will have to assess and manage more patients afflicted with this potentially debilitating condition. We must stay abreast of current and upcoming means to diagnose and manage AMD. For example, technological advances in ocular imaging are allowing for quicker detection of small drusen and RPE abnormalities, earlier detection of GA, and improved visualization of retinal structure that was previously unobservable with funduscopy alone.

Additionally, we are often faced with family members seeking answers to their questions and concerns, and we owe it to them to address their trepidations with accurate information on current and future treatment options. We can only serve the best interest of our patients by arming ourselves with the knowledge and skill necessary to manage dry AMD in this ever-evolving landscape. ■

Dr. Rixon practices at the Memphis VA medical center, where he is the residency coordinator.

Dr. Trevino is an associate professor at the Rosenberg School of Optometry, where he serves as director of Residency Programs and chief of the Ocular Health Service.

Dr. Attar is the director of professional relations and an assistant clinical professor at the University of Pikeville - Kentucky College of Optometry (KYCO).

The authors would like to thank Mohammad Rafieetary, OD, and Jessica Haynes, OD, Optometric Retina Fellow, both at the Charles Retinal Institute, for contributing their expertise to this article.

OSC QUIZ

You can obtain transcript-quality continuing education credit through the Optometric Study Center. Complete the test form, and return it with the $35 fee to: Jobson Medical Information, Dept.: Optometric CE, 440 9th Avenue, 14th Floor, New York, NY 10001. To be eligible, please return the card within one year of publication.

You can also access the test form and submit your answers and payment via credit card at *Review of Optometry* online, www.reviewofoptometry.com. You must achieve a score of 70 or higher to receive credit. Allow eight to 10 weeks for processing. For each Optometric Study Center course you pass, you earn 2 hours of transcript-quality credit from Pennsylvania College of Optometry and double credit toward the AOA Optometric Recognition Award—Category 1.

Please check with your state licensing board to see if this approval counts toward your CE requirement for relicensure.

1. Which of the following is considered the hallmark of early AMD?
a. Choriodal neovascular membrane.
b. Reticular pseudodrusen.
c. Drusen.
d. Geographic atrophy.

2. What are the dimensions of a large drusen?
a. <30µm.
b. ≥30µm to 63µm.
c. ≥63µm to 125µm.
d. >125µm.

3. What are two important risk factors for progression to advanced AMD?
a. Drusen size and pigment abnormalities.
b. Drusen size and age.
c. Drusen size and dietary intake of carotenoids.
d. Drusen size and hypercholesterolemia.

4. Which statement is true regarding OCT imaging in AMD?
a. Pigment clumping and migration appears focally hypo-reflective on OCT.
b. Choroidal changes in AMD cannot be imaged with OCT.
c. Formation of GA can lead to atrophy of the outer retina, which can be visualized with OCT.
d. OCT can only image large drusen.

5. The five-year risk of developing late AMD is greatest with the presence of:
a. Bilateral large drusen.
b. Bilateral presence of both large drusen and pigment abnormalities.
c. Bilateral pigment abnormalities.
d. Bilateral medium drusen.

6. Which statement regarding the natural history of drusen is true?
a. Drusen are not dynamic.
b. Both resorption and development of drusen can occur simultaneously in the same eye.
c. Spontaneous regression of drusen decreases the likelihood of progression to GA or CNV.
d. Those with lower total drusen volume are more likely to have drusen regression.

7. Fundus autofluorescence imaging noninvasively visualizes which of the following?
a. Cholesterol plaques.
b. Edema secondary to CNV.
c. Fluorophores.
d. Intact choroidal vasculature.

8. Which is true regarding current treatment of dry AMD?
a. There are already FDA-approved injectable medications to treat dry AMD.
b. GA has been shown to stabilize with injection of anti-VEGF molecules.
c. Current treatment of dry AMD is limited to lifestyle modifications and vitamin supplementation.
d. There is currently minimal research being done to improve management of dry AMD.

9. What drug class has a potential medication that is currently in phase III clinical trials and has shown potential for reduction of GA progression in phase II trials?
a. Anti-VEGF agents.
b. Anti-angiopoietin 2 agents.
c. Anti-PDFG agents.
d. Complement inhibitors.

10. Which is not a goal for improving treatment of exudative or wet AMD?
a. Allowing for more frequent injections of anti-VEGF agents.
b. Targeting multiple steps in the development of CNV.
c. Developing sustained-release delivery systems.
d. Developing novel anti-VEGF agents that have longer duration of action.

11. Which individual would be at greatest risk of developing AMD?
a. 85-year-old Caucasian non-smoker.
b. 95-year-old Caucasian smoker.
c. 85-year-old African American non-smoker.
d. 95-year-old African American smoker.

12.Which of the following lifestyle changes can decrease AMD risk?
a. Spending more time outdoors.
b. Getting regular exercise.
c. Moderate alcohol consumption.
d. Increased consumption of red meat.

13. Which factor has an established causative relationship with AMD?
a. Cataract surgery.
b. Smoking tobacco products.
c. Egg consumption.
d. Second-hand smoke.

14. Which of the below measures would be least effective at decreasing AMD risk?
a. Smoking cessation.
b. Cataract surgery.
c. Wearing sunglasses outdoors.
d. Lutein supplementation.

15 Factors contributing to low macular

OSC QUIZ

pigment include all of the following except:
a. Genetics.
b. Smoking.
c. Low dietary intake of lutein and zeaxanthin.
d. Sun exposure.

16. Which of the following are macular pigments?
a. Zeaxanthin and canthaxanthin.
b. Porphyrin and nasturtium.
c. Lutein and zeaxanthin.
d. Melanin and rhodopsin.

17. The exam frequency for a high-risk AMD patient with soft confluent drusen and granular pigmentary degeneration should be:
a. Every three months.
b. Annually.
c. Four to six months.
d. Every two years.

18. Which of the following is not a potential factor contributing to the scotopic dysfunction in early AMD?
a. Development of intraretinal pigmentary deposits.
b. Genetic alterations in vitamin A metabolism.
c. Age- and disease-related deficits in pathways within the RPE metabolism.
d. A disruption in the retinoid cycle.

19. Which two genes are associated with high risk of AMD development?
a. CYP1B1 and ARMS2.
b. ARMS2 and CFH.
c. PAX6 and CYP1B1.
d. CFH and PAX6.

20. The recommended management plan for a patient with two or more risk factors for AMD and over the age of 55 include all of the following except:
a. Antioxidant supplementation.
b. Home Amsler or comparable monocular near vision self-monitoring weekly.
c. UVR protection.
d. Low vision consultation and evaluation.

TAKE THE TEST ONLINE TODAY!
www.reviewofoptometry.com/continuing_education/

Examination Answer Sheet

Valid for credit through January 1, 2020

This exam can be taken online at www.revoptom.com/continuing_education. Upon passing the exam, you can view your results immediately and download a real-time CE certificate. You can also view your test history at any time from the website.

Arm Yourself for Dry AMD

Directions: Select one answer for each question in the exam and completely darken the appropriate circle. A minimum score of 70% is required to earn credit.

Mail to: Jobson Medical Information, Dept.: Optometric CE, 440 9th Avenue, 14th Floor, New York, NY 10001.

Payment: Remit $35 with this exam. Make check payable to Jobson Medical Information LLC.

COPE approved for 2 hours of CE credit. COPE ID is 51947-PS.

This course is joint-sponsored by the Pennsylvania College of Optometry

There is an eight-to-ten week processing time for this exam.

1.	Ⓐ	Ⓑ	Ⓒ	Ⓓ
2.	Ⓐ	Ⓑ	Ⓒ	Ⓓ
3.	Ⓐ	Ⓑ	Ⓒ	Ⓓ
4.	Ⓐ	Ⓑ	Ⓒ	Ⓓ
5.	Ⓐ	Ⓑ	Ⓒ	Ⓓ
6.	Ⓐ	Ⓑ	Ⓒ	Ⓓ
7.	Ⓐ	Ⓑ	Ⓒ	Ⓓ
8.	Ⓐ	Ⓑ	Ⓒ	Ⓓ
9.	Ⓐ	Ⓑ	Ⓒ	Ⓓ

19.	Ⓐ	Ⓑ	Ⓒ	Ⓓ
20.	Ⓐ	Ⓑ	Ⓒ	Ⓓ

1 = Excellent 2 = Very Good 3 = Good 4 = Fair 5 = Poor

Rate the effectiveness of how well the activity:

21. Met the goal statement: ① ② ③ ④ ⑤
22. Related to your practice needs: ① ② ③ ④ ⑤
23. Will help you improve patient care: ① ② ③ ④ ⑤
24. Avoided commercial bias/influence: ① ② ③ ④ ⑤
25. How would you rate the overall quality of the material presented? ① ② ③ ④ ⑤
26. Your knowledge of the subject was increased:
◯ Greatly ◯ Somewhat ◯ Little
27. The difficulty of the course was:
◯ Complex ◯ Appropriate ◯ Basic

How long did it take to complete this course?
